

## Harold's Descriptive Statistics Cheat Sheet

21 October 2024

### Descriptive

Description	Population	Sample	Used For
Data	Parameters	Statistics	Describing and predicting.
Random Variable	$X, Y$	$x, y$	The random value from the evaluated population.
Size	$N$	$n$	Number of observations in the population / sample.

Measures of Center		(Measure of central tendency)	Indicates which value is typical for the data set.
Mean	$\mu = \frac{1}{N} \sum_{i=1}^N x_i f$ <p><math>f = 1</math> if samples are unordered</p>	$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i f$ $n = \sum f$	Measure of center for unordered and frequency distributions. Average, arithmetic mean. Used when same probabilities for each X. Answers "Where is the center of the data located?"
Weighted Mean	$\mu = \frac{\sum a_i x_i}{\sum a_i}$	$\bar{x} = \frac{\sum a_i x_i}{\sum a_i}$	Some values are counted more than once. $a_i$ = positive integer or percentage.
Median	$Md = \frac{n+1}{2} \text{ if } n \text{ is odd}$	$Md = \frac{n}{2} + 1 \text{ if } n \text{ is even}$	The middle element in a <u>sorted</u> dataset. More useful when data are skewed with outliers.
Mode	$Mo = \max(f)$	Appropriate for categorical data.	The most frequently-occurring value in a dataset.
Mid-Range	$MidRange = \frac{max. + min.}{2}$	Not often used, easy to compute.	Highly sensitive to unusual values.
Python	<pre>import pandas as pd data = pd.read_csv('file.csv') print(data.mean()) print(data[['Header1']].median()) print(data[['Header1', 'Header2']].mode()) mid_range = (data.min() + data.max()) / 2.0</pre>		

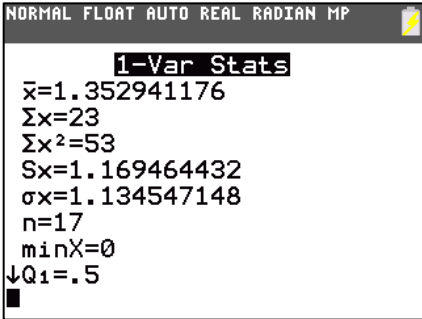

Description	Population	Sample	Used For
<b>Measures of Dispersion</b>		(Measure of dispersion, variability, or spread of the distribution)	Reflect the variability of the data (e.g. how different the values are from each other).
<b>Variance</b>	$\sigma^2 = \frac{1}{N} \sum (x_i - \mu)^2 f$ $\sigma^2 = \frac{1}{N} \left( \sum_{i=1}^N f x_i^2 - N \mu^2 \right)$	$s^2 = \frac{1}{n-1} \sum (x_i - \bar{x})^2 f$ $s^2 = \frac{1}{n-1} \left( \sum_{i=1}^n f x_i^2 - n \bar{x}^2 \right)$	The average of the sum of the square differences. Not often used. See standard deviation. Special case of covariance when the two variables are identical.
<b>Covariance</b>	$\sigma(X, Y) = \frac{1}{N} \sum (x - \mu_x)(y - \mu_y)$ $\sigma(X, Y) = \frac{1}{N} \sum x_i y_i - \mu_x \mu_y$	$g = \frac{1}{n-1} \sum (x - \bar{x})(y - \bar{y})$ $\sigma(x, y) = \frac{1}{n-1} \left( \sum_{i=1}^n x_i y_i - n \bar{x} \bar{y} \right)$	A measure of how much two random variables change together. Measure of “linear dependence”. If X and Y are independent, then their covariance is zero (0).
<b>Standard Deviation</b>	$\sigma = \sqrt{\sigma^2} = \sqrt{\frac{\sum (x_i - \mu)^2}{N}}$ $\sigma = \sqrt{\frac{\sum x_i^2}{N} - \mu^2}$	$s_x = \sqrt{\frac{\sum (x_i - \bar{x})^2}{n-1}}$ $s = \sqrt{\frac{\sum x_i^2 - n \bar{x}^2}{n-1}}$	Measure of variation; average distance from the mean. Same units as mean. Answers “How spread out is the data?”
<b>Mean Absolute Deviation</b>	$MAD = \frac{1}{N} \sum  x_i - \mu $	$MAD = \frac{1}{n} \sum  x_i - \bar{x} $	Uses the absolute value instead of the square root of a sum of squares to avoid negative distances.
<b>Pooled Standard Deviation</b>	$\sigma_p = \sqrt{\frac{N_1 \sigma_1^2 + N_2 \sigma_2^2}{N_1 + N_2}}$	$s_p = \sqrt{\frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{(n_1 - 1) + (n_2 - 1)}}$	Inferences for two population means.
<b>Interquartile Range (IQR)</b>	$IQR = Q3 - Q1$		Less sensitive to extreme values.
<b>Range</b>	$Range = max. - min.$	Not often used, easy to compute.	Highly sensitive to unusual values.
<b>Python</b>	<pre>import pandas as pd data = pd.read_csv('file.csv') print(data.var()) print(data.cov()) print(data.std())</pre>		<pre>print(data.mad()) def IQR(data):     # (import numpy as np)     Q3 = np.quantile(data, 0.75)     Q1 = np.quantile(data, 0.25)     IQR = Q3 - Q1     range = data.max() - data.min()</pre>

Description	Population	Sample	Used For
<b>Measures of Relative Standing</b>		(Measures of relative position)	Indicates how a particular value compares to the others in the same data set.
<b>Percentile</b>	Data divided onto 100 equal parts by rank.		Important in normal distributions.
<b>Quartile</b>	Data divided onto 4 equal parts by rank.		Used to compute IQR.
<b>Z-Score / Standard Score / Normal Score</b>	$x = \mu + z \sigma$ $z = \frac{x - \mu}{\sigma}$	$x = \bar{x} + z s$ $z = \frac{x - \bar{x}}{s}$	The $z$ variable measures how many standard deviations the value is away from the mean. Rule of Thumb: Outlier if $ z  > 2$ .
<b>Calculator (TI-84)</b>	[2 <sup>nd</sup> ][VARS][2] normalcdf(-1E99, z)		
<b>Python</b>	<pre>import scipy.stats as st  mean, sd, z = 0, 1, 1.5 print(st.norm.cdf(z, mean, sd))      # P(z &lt;= 1.5) print(st.norm.sf(z, mean, sd))      # P(z &gt;= 1.5)  mean, sd, x = 55, 7.5, 62 print(st.norm.cdf(x, mean, sd))     # P(x &lt;= 62) print(st.norm.sf(x, mean, sd))     # P(x &gt;= 62)</pre>		0.9331927987311419 0.0668072012688580  0.8246760551477705 0.1753239448522295

## Regression and Correlation

Description	Formula	Used For
Response Variable	$Y$	Output
Covariate / Predictor Variable	$X$	Input
Least-Squares Regression Line	$\hat{y} = b_0 + b_1x$	$b_1$ is the slope $b_0$ is the y-intercept $(\bar{x}, \bar{y})$ is always a point on the line
Regression Coefficient (Slope)	$b_1 = \frac{\sum(x_i - \bar{x})(y_i - \bar{y})}{\sum(x - \bar{x})^2}$ $b_1 = r \frac{s_y}{s_x}$	$b_1$ is the slope
Regression Slope Intercept	$b_0 = \bar{y} - b_1\bar{x}$	$b_0$ is the y-intercept
Linear Correlation Coefficient (Sample)	$r = \frac{1}{n-1} \sum \left( \frac{x - \bar{x}}{s_x} \right) \left( \frac{y - \bar{y}}{s_y} \right)$ $r = \frac{g}{s_x s_y}$	Strength and direction of linear relationship between x and y.  $r = \pm 1$ Perfect correlation $r = +0.9$ Positive linear relationship $r = -0.9$ Negative linear relationship $r = \sim 0$ No relationship $r \geq 0.8$ Strong correlation $r \leq 0.5$ Weak correlation  Correlation DOES NOT imply causation.
Residual	$\hat{e}_i = y_i - \hat{y}$ $\hat{e}_i = y_i - (b_0 + b_1 x)$ $\sum e_i = \sum (y_i - \hat{y}_i) = 0$	Residual = Observed – Predicted
Standard Error of Regression Slope	$s_{b_1} = \frac{\sqrt{\frac{\sum e_i^2}{n-2}}}{\sqrt{\sum(x_i - \bar{x})^2}}$ $s_{b_1} = \frac{\sqrt{\frac{\sum(y_i - \hat{y}_i)^2}{n-2}}}{\sqrt{\sum(x_i - \bar{x})^2}}$	 <p>Residuals are shown in RED</p>
Coefficient of Determination	$r^2$	How well the line fits the data.  Represents the <b>percent</b> of the data that is the closest to the line of best fit. Determines how certain we can be in making predictions.

## Proportions

Description	Population	Sample	Used For
Proportion	$P = p = \frac{x}{N}$	$\hat{p} = \frac{x}{n}$	Probability of <b>success</b> . The proportion of elements that has a particular attribute (x).
	$q = 1 - p$ $Q = 1 - P$	$\hat{q} = 1 - \hat{p}$	Probability of <b>failure</b> . The proportion of elements in the population that does not have a specified attribute.
Variance of Population (Sample Proportion)	$\sigma^2 = \frac{pq}{N}$ $\sigma^2 = \frac{p(1-p)}{N}$	$s_p^2 = \frac{\hat{p}\hat{q}}{n-1}$ $s_p^2 = \frac{\hat{p}(1-\hat{p})}{n-1}$	Considered an unbiased estimate of the true population or sample variance.
Pooled Proportion	NA	$\hat{p}_p = \frac{x_1 + x_2}{n_1 + n_2}$ $\hat{p}_p = \frac{\hat{p}_1 n_1 + \hat{p}_2 n_2}{n_1 + n_2}$	$x = \hat{p}n$ = frequency, or number of members in the sample that have the specified attribute.

## Discrete Random Variables

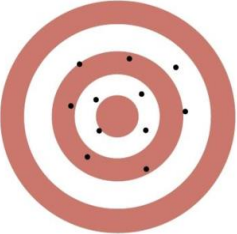

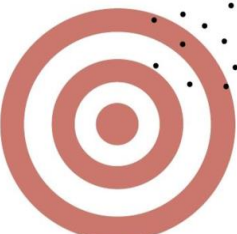

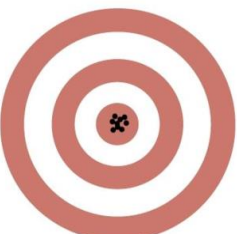

Description	Formula	Used For
Random Variable	$X$	A rule that assigns a number to every <b>outcome</b> in the sample space, S. <i>e.g.,</i> $X(a, b) = a + b = r$ Derived from a probability experiment with different probabilities for each X. <b>Used in discrete or finite PDFs.</b>
Event	$X = r$ $X(s) = r$	An event assigns a value to the random variable X with probability: $P(X = r)$
Expected Value of X	$E[X] = \bar{x}$ or $\mu_x$ Each event: $E[X] = \sum P(X) \cdot X$ $E[X] = \sum_{s \in S} X(s) \cdot P(s)$ Groups of like events: $E[X] = \sum_{i=1}^N p_i(x) \cdot x_i$ $E[X] = \sum_{r \in X(S)} r \cdot P(X = r)$	E(X) is the same as the mean or average. X takes some countable number of specific values. Discrete. Expectation of a random variable. $P(s)$ = probability of outcome s from S.
Linearity of Expectations	$E[X + Y] = E[X] + E[Y]$ $E[X + Y + Z] = E[X] + E[Y] + E[Z]$ $E[cX] = cE[X]$	When carefully applied, linearity of expectations can greatly simplify calculating expectations.  Does not require that the random variables be independent.
Variance of X	$V(X) = \sigma_x^2 = \sum p_i(x) \cdot (x_i - \mu_x)^2$ $\sigma_x^2 = \sum P(X) \cdot (X - E[X])^2$ $\sigma_x^2 = \sum X^2 \cdot P(X) - E[X]^2$ $\sigma_x^2 = E[X^2] - E[X]^2$	Calculate variances with proportions or expected values.
Standard Deviation of X	$SD(X) = \sqrt{V(X)}$ $\sigma_x = \sqrt{\sigma_x^2}$	Calculate standard deviations with proportions.
Sum of Probabilities	$\sum_{i=1}^N p_i(x) = 1$	If same probability, then $p_i(x) = \frac{1}{N}$ .

NOTE: See also "Discrete Definitions" on [Harold's Stats Distributions Cheat Sheet](#).

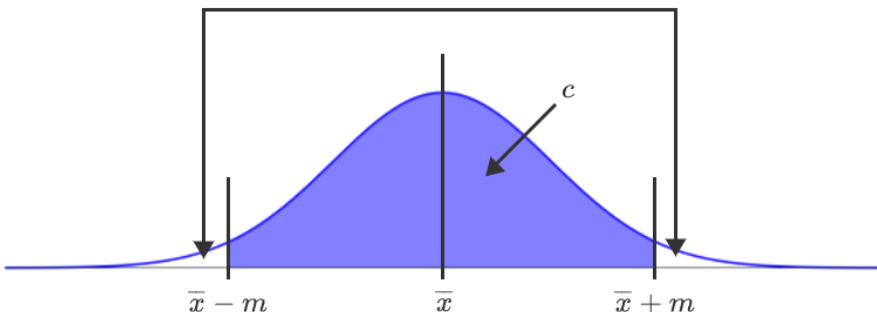

## Sampling Distribution Statistical Inference

Description	Mean	Standard Deviation
<b>Sampling Distribution</b>	Is the probability distribution of a statistic; a statistic of a statistic.	
<b>Central Limit Theorem (CLT)</b>	$PDF(\bar{x}) \approx \mathcal{N}\left(0, \frac{\sigma^2}{n}\right)$	As the sample size drawn from the population with distribution <b>X</b> becomes larger, the sampling distribution of the means $\bar{X}$ approaches that of a normal distribution $\mathcal{N}\left(0, \frac{\sigma^2}{n}\right)$ .
<b>Sample Mean</b>	$\mu_{\bar{x}} = \mu$	<p>Sampling with replacement:</p> $\sigma_{\bar{x}} = \frac{\sigma}{\sqrt{n}}$ <p>Sampling without replacement:</p> $\sigma_{\bar{x}} = \sqrt{\frac{N-n}{N-1}} \cdot \frac{\sigma}{\sqrt{n}}$ <p>(2x accuracy needs 4x n)</p>
z-Score	$z = \frac{\bar{x} - \mu_{\bar{x}}}{\sigma_{\bar{x}}}$	$z = \frac{\bar{x} - \mu}{\sigma / \sqrt{n}}$
Sample Mean Rule of Thumb	Use if $n \geq 30$ <b>or</b> if the population distribution is normal	
10% Condition	$n \leq \frac{N}{10}$ . Sample size must be at most 10% of the population size.	
<b>Sample Proportion</b>	$\mu = p$	$\sigma_p = \sqrt{\frac{p(1-p)}{n}}$
z-Score	$z = \frac{\hat{p} - \mu}{\sigma_p}$	$z = \frac{\hat{p} - p}{\sqrt{\frac{p(1-p)}{n}}}$
Sample Proportion Rule of Thumb	<p>Large Counts Condition:</p> <p>Use if <math>np \geq 5</math> <b>and</b> <math>n(1-p) \geq 5</math></p> <p>Use if <math>np \geq 10</math> <b>and</b> <math>n(1-p) \geq 10</math></p>	
<b>Difference of Sample Means</b>	$E(\bar{x}_1 - \bar{x}_2) = \mu_{\bar{x}_1} - \mu_{\bar{x}_2}$	$\sigma_{\bar{x}_1 - \bar{x}_2} = \sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}$
Special case when $\sigma_1 = \sigma_2$		$\sigma_{\bar{x}_1 - \bar{x}_2} = \sigma \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}$
<b>Difference of Sample Proportions</b>	$\Delta \hat{p} = \hat{p}_1 - \hat{p}_2$	$\sigma = \sqrt{\frac{p_1(1-p_1)}{n_1} + \frac{p_2(1-p_2)}{n_2}}$
Special case when $p_1 = p_2$		$\sigma = \sqrt{p(1-p)} \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}$

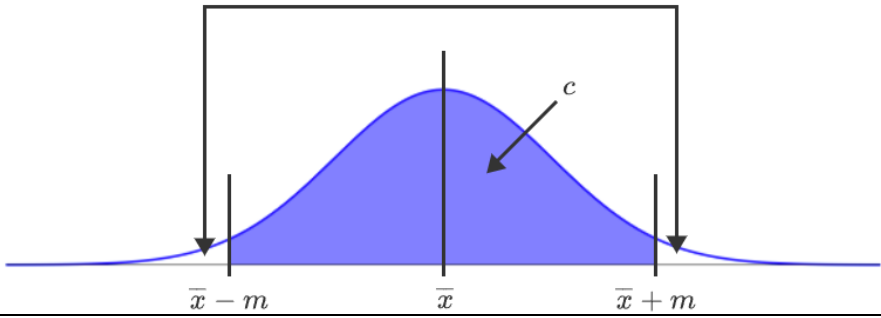

<b>Bias</b>	<p>Caused by non-random samples.</p> <p><u>Selection Bias</u>: Under coverage, Nonresponse, Voluntary response</p> <p><u>Response Bias</u>: Acquiescence, Extreme, Social desirability</p>	 <p>High bias, low variability (a)</p>  <p>Low bias, high variability (b)</p>
<b>Variability</b>	<p>Caused by too small of a sample. <math>n &lt; 30</math></p> <p><u>Sampling Methods</u>: Simple random, systematic, stratified, cluster, convenience</p>	 <p>High bias, high variability (c)</p>  <p>The ideal: low bias, low variability (d)</p>

## Confidence Intervals for One Population Mean / Proportion ( $\sigma$ is Known)

Description	Formula									
Critical Value (z*)	Usually set ahead of time, unless using p-values to determine.									
	Set to a threshold value of 0.05 (5%) or 0.01 (1%), but always ≤ 0.10 (10%).									
		<table><tr><th>Confidence Level</th><th>Critical Value</th></tr><tr><td>c = 0.90</td><td>z* = 1.645</td></tr><tr><td>c = 0.95</td><td>z* = 1.960</td></tr><tr><td>c = 0.99</td><td>z* = 2.576</td></tr></table>	Confidence Level	Critical Value	c = 0.90	z* = 1.645	c = 0.95	z* = 1.960	c = 0.99	z* = 2.576
	Confidence Level	Critical Value								
c = 0.90	z* = 1.645									
c = 0.95	z* = 1.960									
c = 0.99	z* = 2.576									
p-value	Probability of obtaining a sample “more extreme” than the ones observed in your data, assuming H <sub>0</sub> is true.									
Sample Size (for estimating μ)	$n = \left(\frac{z^* \sigma}{SE}\right)^2 = \left(\frac{z^*}{SE}\right)^2 p(1 - p)$ <p>The size of the sample needed to guarantee a confidence interval with a specified margin of error. Rounded up to the nearest whole number.</p>									
Margin of Error / Standard Error (SE) (for the estimate of μ)	$SE(\bar{x}) = m = z^* \frac{\sigma}{\sqrt{n}} = z^* \sqrt{\frac{p(1 - p)}{n}}$ <p>The estimate <math>\bar{x}</math> differs from the actual value by at most SE. Use p = 0.50 for worst case if no previous estimate is known.</p>									
	SE with replacement: $\sigma_{\bar{x}} = \frac{\sigma}{\sqrt{n}} = \sqrt{\frac{p(1 - p)}{n}}$	SE without replacement (with correction factor): $\sigma_{\bar{x}} = \sqrt{\frac{N - n}{N - 1}} \cdot \frac{\sigma}{\sqrt{n}}$								
Confidence Interval for μ (z interval) (σ known, normal population or large sample)	$z \text{ interval} = \text{statistic} \pm (\text{critical value}) \cdot (\text{SD of statistic})$ $z \text{ interval} = \bar{x} \pm SE(\bar{x})$ $\bar{x} \pm m = [\bar{x} - m, \bar{x} + m]$ $z \text{ interval} = \bar{x} \pm z^* \frac{\sigma}{\sqrt{n}} = \bar{x} \pm z^* \sqrt{\frac{p(1 - p)}{n}}$ <div></div> $\frac{\alpha}{2} = \frac{1 - c}{2}$ <p><math>z^* = z \text{ score for probabilities of } \alpha/2 \text{ (two - tailed)}</math></p>									
	Standardized Test Statistic (of the variable $\bar{x}$ from the CLT)	$z = \frac{\text{statistic} - \text{parameter}}{\text{SD of statistic}}$ $z = \frac{\bar{x} - \mu}{\sigma / \sqrt{n}}$								

## Confidence Intervals for One Population Mean / Proportion ( $\sigma$ is Unknown)

Description	Formula				
Critical Value (t*)	Usually set ahead of time, unless using p-values to determine. $df = n-1$ .  Set to a threshold value of 0.05 (5%) or 0.01 (1%), but always $\leq 0.10$ (10%).	df	$\alpha = 0.10$	$\alpha = 0.05$	$\alpha = 0.01$
		5	2.015	2.571	4.032
		10	1.812	2.225	3.169
		15	1.753	2.131	2.947
		24	1.711	2.064	2.797
32	1.309	1.694	2.449		
p-value	Probability of obtaining a sample “more extreme” than the ones observed in your data, assuming $H_0$ is true.				
Sample Size (for estimating $\mu$ )	Preliminary estimate of n: $n^* = \left(\frac{z^*s}{SE}\right)^2$				
	Actual sample size, n: $n = \left(\frac{t^*s}{SE}\right)^2$				
	The size of the sample needed to guarantee a confidence interval with a specified margin of error. Rounded up to the nearest whole number.				
Margin of Error / Standard Error (SE) (for the estimate of $\mu$ )	$SE(\bar{x}) = m = t^* \frac{s}{\sqrt{n}}$ The estimate $\bar{x}$ differs from the actual value by at most SE.				
	SE with replacement: $s_{\bar{x}} = \frac{s}{\sqrt{n}}$		SE without replacement (with correction factor): $s_{\bar{x}} = \sqrt{\frac{N-n}{N-1}} \cdot \frac{s}{\sqrt{n}}$		
Confidence Interval for $\mu$ (t interval) ( $\sigma$ unknown, t distribution or small sample)	$t \text{ interval} = \text{statistic} \pm (\text{critical value}) \cdot (SD \text{ of statistic})$  $t \text{ interval} = \bar{x} \pm SE(\bar{x})$ $\bar{x} \pm m = [\bar{x} - m, \bar{x} + m]$ $t \text{ interval} = \bar{x} \pm t^* \frac{s}{\sqrt{n}}$ <div><math display="block">\alpha</math></div>				
	$t = \frac{\text{statistic} - \text{parameter}}{SD \text{ of statistic}}$  $t = \frac{\bar{x} - \mu}{s/\sqrt{n}}$				

## Confidence Intervals for the Difference Between Two Population Means / Proportions ( $\sigma$ is Known)

Description	Formula									
Critical Value (z*)	Usually set ahead of time, unless using p-values to determine.	<table><tr><th>Confidence Level</th><th>Critical Value</th></tr><tr><td>c = 0.90</td><td>z* = 1.645</td></tr><tr><td>c = 0.95</td><td>z* = 1.960</td></tr><tr><td>c = 0.99</td><td>z* = 2.576</td></tr></table>	Confidence Level	Critical Value	c = 0.90	z* = 1.645	c = 0.95	z* = 1.960	c = 0.99	z* = 2.576
	Confidence Level	Critical Value								
	c = 0.90	z* = 1.645								
	c = 0.95	z* = 1.960								
c = 0.99	z* = 2.576									
	Set to a threshold value of 0.05 (5%) or 0.01 (1%), but always ≤ 0.10 (10%).									
p-value	TI-84: DISTR 2: normalcdf(z_test, 99999999) = p									
Margin of Error / Standard Error (SE) (for the estimate of μ)	$E(\bar{x}_1 - \bar{x}_2) = \mu_{\bar{x}_1} - \mu_{\bar{x}_2}$ $SE(\bar{x}_1 - \bar{x}_2) = \sqrt{SE_1^2 + SE_2^2} = m$ $= \sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}} = \sqrt{\frac{p_1(1 - p_1)}{n_1} + \frac{p_2(1 - p_2)}{n_2}} = \sqrt{\hat{p}(1 - \hat{p})} \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}$ <p><math>\hat{p}</math> = Overall probability of success when the two samples are combined. The estimate <math>\bar{x}_1 - \bar{x}_2</math> differs from the actual value by at most SE. Use p = 0.50 for worst case if no previous estimate is known.</p>									
Confidence Interval for μ (z interval) (σ known, normal population or large sample)	$z \text{ interval} = \text{statistic} \pm (\text{critical value}) \cdot (SD \text{ of statistic})$ $z \text{ interval} = (\bar{x}_1 - \bar{x}_2) \pm SE(\bar{x}_1 - \bar{x}_2)$ $(\bar{x}_1 - \bar{x}_2) \pm m = [(\bar{x}_1 - \bar{x}_2) - m, (\bar{x}_1 - \bar{x}_2) + m]$ $z \text{ interval} = (\bar{x}_1 - \bar{x}_2) \pm z^* \sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}$ $z \text{ interval} = (\bar{x}_1 - \bar{x}_2) \pm z^* \sqrt{\frac{p_1(1 - p_1)}{n_1} + \frac{p_2(1 - p_2)}{n_2}}$ $\frac{\alpha}{2} = \frac{1 - c}{2}$ <p><math>z^*</math> = z score for probabilities of <math>\alpha/2</math> (two – tailed)</p>									
Standardized Test Statistic (of the variable $\bar{x}$ from the CLT)	$z = \frac{\text{observed difference} - \text{hypothesized difference}}{SD \text{ for the difference}}$ $z = \frac{(\bar{x}_1 - \bar{x}_2) - 0}{\sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}}$

## Confidence Intervals for the Difference Between Two Population Means / Proportions ( $\sigma$ is Unknown)

Description		Formula				
Critical Value (t*)		Usually set ahead of time, unless using p-values to determine. $df = n-1$ .  Set to a threshold value of 0.05 (5%) or 0.01 (1%), but always $\leq 0.10$ (10%).	df	$\alpha = 0.10$	$\alpha = 0.05$	$\alpha = 0.01$
			5	2.015	2.571	4.032
			10	1.812	2.225	3.169
			15	1.753	2.131	2.947
			24	1.711	2.064	2.797
			32	1.309	1.694	2.449
p-value		TI-84: DISTR 6: tcdf(t_test, 99999999) = p				
Margin of Error / Standard Error (SE) (for the estimate of $\mu$ )		$SE(\bar{x}_1 - \bar{x}_2) = m = \frac{s_d}{\sqrt{n}}$ The estimate $\bar{x}_1 - \bar{x}_2$ differs from the actual value by at most SE.				
Confidence Interval for $\mu$ (t interval) ( $\sigma$ unknown, t distribution or small sample)		$t \text{ interval} = \text{statistic} \pm (\text{critical value}) \cdot (\text{SD of statistic})$  $t \text{ interval} = (\bar{x}_1 - \bar{x}_2) \pm \frac{s_d}{\sqrt{n}}$				
Standardized Test Statistic (of the variable $\bar{x}$ from the CLT)		$t = \frac{\text{mean difference between samples} - \text{parameter}}{\text{sample SD of the differences} / \sqrt{n}}$  Paired t-test:  $t = \frac{\bar{d} - \mu_d}{s_d / \sqrt{n}}$ $df = n - 1$  Unpaired t-test:  $t = \frac{(\bar{x}_1 - \bar{x}_2) - (\mu_1 - \mu_2)}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}}$ $df = n_1 + n_2 - 2$  $t = \frac{\hat{p}_1 - \hat{p}_2}{SE}$				
Python	Paired	<pre>import scipy.stats as st import pandas as pd df = pd.read_csv('ExamScores.csv') st.ttest_rel(df['Exam1'],df['Exam2'])</pre>		Ttest_relResult (statistic = 1.4179, pvalue = 0.16254)		
	Unpaired	<pre>import scipy.stats as st import pandas as pd df = pd.read_csv('Machine.csv') st.ttest_ind(df['Old'],df['New'], equal_var=False))</pre>		Ttest_indResult (statistic = 3.3972, pvalue = 0.00324)		
	<pre>from statsmodels.stats.proportion import proportions_ztest counts = [95, 125] n = [5000, 5000] print(proportions_ztest(counts, n))</pre>		(statistic = -2.04522, pvalue = 0.04083)
